Technology occupies a large place in the life of people. It began to be introduced from the last century and now technological progress has reached unprecedented heights. It's about computers. There are ardent opponents of using computers, which consider that it is more useful to do anything than sit at a computer. Harmful radiation from the monitors, and the lack of mobility that they cause, and the nerves spent on repairs and maintenance, computer games that kill the younger generation - all hurt!

Let's talk about the advantages of using a computer. Computers are a great tool for getting new information. When you connect to the Internet and have the right set of programs, getting new knowledge becomes much easier than before. Simple operations such as clicks and a set of search queries replace information retrieval in libraries and local research networks. Computers really are powerful computing tools. By themselves, computer technology is aimed at the development of electronic computing and the transfer of everyday tasks from human shoulders. Modern processors, on which the computing power of the computer is based, are capable of performing millions of simple operations per second, providing much higher speed in solving complex problems. The computer laid the foundations for a mass media network that also serves as a separate market with exchanges and vacancies, an entertaining platform and a center for the concentration of scientific knowledge.

As a result, computers, contrary to popular belief, are not anything that has a destructive effect on man and mankind. For the history of their development, they have become safer, more powerful, more functional and cheaper. The PC's are mostly subjective and in the near future we will observe their disappearance.
